Commercial and Recreational Data Collection and Analysis

Anthony Wood, NOAA Fisheries

TOR#2: Estimate catch from all sources including landings and discards. Describe the spatial and temporal distribution of landings, discards, and fishing effort. Characterize the uncertainty in these sources of data.

1.1 Commercial Data

1.1.1 Commercial Data Information

Historical commercial landings (1950 to present) for all species on the Atlantic coast are maintained in the Atlantic Coastal Cooperative Statistics Program (ACCSP) Warehouse. The Data Warehouse is an online database of fisheries dependent data provided by the ACCSP state and federal partners. The Data Warehouse was queried on 31 May 2022 for all commercial bluefish landings (monthly summaries by state, gear and market category) from 1985-2021 for Florida (east coast), Georgia, South Carolina, North Carolina, Virginia, Maryland, Delaware, New Jersey, New York, Connecticut, Rhode Island, Massachusetts, New Hampshire, and Maine. Data sources and collection methods are illustrated by state in Figure 1, and annual landings summaries were used when trip level data or monthly summaries were not available. The gear categories were decided upon by the working group based on knowledge of the fisheries and reporting tendencies. The specific ACCSP gears included in each category can be found in Table 1.

After review of the commercial landings data by ACCSP state partners during the benchmark assessment in 2015, differences in the annual landings from 1996-2014 were identified between the Virginia Fishery Mandatory Reporting Program Trip (FSMRPT) historical landings database and the ACCSP data warehouse. Issues such as duplicate state and federal reporting of landings, and failure to sync data across programs when records are updated in local databases, may be responsible for the discordance across the federally reported and state reported commercial bluefish landings, and the Potomac River Fisheries Commission (PRFC) data, between the Virginia historical landings database and the ACCSP data warehouse. The difference in total commercial bluefish landings between the ACCSP data warehouse and Virginia historical landings database was approximately 1.5% from 1982-2014. At this time, ACCSP provided two datasets as options to be used in the assessment model for the Virginia commercial landings data for bluefish. Option 1 consisted of commercial bluefish landings where each year of data from 1982-2014 was chosen from either the ACCSP data warehouse or the VA historical landings database, depending on which of these two had the greater annual landings total. Option 2 consisted of commercial bluefish landings where the annual federal dealer landings, the annual state dealer landings, and the PRFC data were compared separately for each year from 1982-2014, and the greater selected from either the ACCSP data warehouse or the VA historical landings database. Both of the options tended towards the creation of larger datasets in order to avoid underrepresenting the Virginia commercial bluefish landings data in the assessment. The 2015 benchmark working group decided to move forward with the option 1 calculations for Virginia landings. Option 1 has been maintained since 2015 and was maintained for the 2022 bluefish research track assessment to derive commercial bluefish landings for Virginia.

Prior to the SARC 60 benchmark in 2015, the commercial landings data had been provided by the Northeast Fisheries Science Center (NEFSC) Commercial Fisheries Database (CFDBS) area allocation (AA) tables, and supplemented with state data supplied directly from several local state collection programs. For past bluefish assessment updates, the NEFSC CFDBS AA tables were queried for the federal dealer reported landings and length data from Maine to Maryland, and occasionally for Virginia landings data for some years. However, these NEFSC CFDBS data did not capture the commercial bluefish landings reported by state dealers without federal reporting requirements. Therefore, it was necessary that additional state

dealer reported landings and length data would be supplied by the Virginia Marine Resources Commission (VMRC), the North Carolina Department of Marine Fisheries (NCDMF) trip ticket program, and the Florida Fish and Wildlife Conservation Commission (FWC). To improve on the consistency and reproducibility of the data collection for future bluefish assessments, it was decided for SARC 60 that the commercial bluefish landings would be supplied by the ACCSP data warehouse, which maintains fisheries dependent data for all Atlantic coast species across all ACCSP state and federal partners.

In 2019, the NEFSC and partners initiated the development of a new Catch Accounting and Monitoring System (CAMS) which could be used to provide bluefish commercial landings going forward. The Catch Accounting and Monitoring System (CAMS) is designed to provide a single, comprehensive source for all US commercial catch (landings and discards) for quota monitoring, stock assessment, protected resource estimation, ecosystem modeling, and other needs of GARFO and NEFSC in a fully documented relational database with appropriate user views and tables. As of 2020, the NEFSC has halted production of the CFDBS AA tables and landings are now provided by the new CAMS system. The entire CAMS system will undergo a full peer review in 2023.

At present, there exists single year of overlap (2019) where comparisons between the old AA table algorithms and the new CAMS system is possible. A comparison of 2019 bluefish commercial landings from the CFDBS_AA tables, CAMS, and ACCSP shows consistency across the sources for most of the State landings data. Differences in FL, NC, and VA persist between information in CAMS and ACCSP. Both NC and FL have provided additional state dealer reported landings which may not be accounted for by the new CAMS process. In addition, Virginia state landings have historically shown the greatest disparity when compared to the AA table landings. This disparity is still present in the 2019 comparison with both the AA table and CAMS results (Table 2, Figure 2). For the 2022 RT the WG decided to maintain the use of ACCSP to provide commercial landings data. CAMS will be considered in the future following its peer review, and when more years of comparison are available.

Commercial fisheries landings data for states between North Carolina and Maine are collected via the NMFS dealer mandatory reporting system. Beginning in June 2004, an electronic dealer reporting was initiated in the northeast. The states of Florida, Georgia, and South Carolina use a trip ticket system.

1.1.2 Commercial Landings

Over the last 40 years, commercial landings from the bluefish fishery ranged from a high of 7,166 MT (15.8 million pounds) in 1983 and have steadily declined to a low of 1,089 MT (2.4 million pounds) in 2021 (Table 3, Figure 3). During this time commercial landings have been consistently lower than the recreational catch and accounted for on average ~XX% of the total catch on (Figure X). Amendment 1 to the bluefish FMP was implemented in the year 2000 and the commercial fishery has been regulated by quota since this time. Gill nets are the dominant commercial gear used to target bluefish and account for an average of over 50% of the bluefish commercial landings from 1982 to 2021, with primary use in the Mid-Atlantic and Florida. Other commercial gears including hook & line, pound nets, seines, and trawls, collectively account for approximately 50% of the commercial landings (Table 4).

Regional variations in commercial fishing activity are linked to the seasonal migration of bluefish. The majority of commercial fishing activity in the North and Mid-Atlantic occurs from late spring to early fall when bluefish are most abundant in these areas. As water temperatures decrease in late fall and winter, bluefish migrate south. Peak landings in the South Atlantic occur in late fall and winter. The majority of commercial landings over the time series (1950-present) have been taken in the Mid-Atlantic region (New York, New Jersey, and North Carolina), with the exception of Florida which accounted for a larger percent

historically (early 1980s) and a diminishing proportion of landings over time (Table 3). Since 1982, approximately 65% of the coast-wide total landings have been taken in this from these 3 states.

The Northeast Region is divided into 46 statistical areas for Federal fisheries management. According to VTR data, bluefish were commercially harvested in 36 statistical areas in 2021. Six statistical areas, however, collectively accounted for more than 75 % of VTR-reported landings in 2021, with individual areas contributing 6% to 18% of the total (Table X). This trend is supported through time by VTR trip and catch data over the last 29 years (Figures 4-8). These areas also represented 70% of the trips that landed bluefish suggesting that resource availability as expressed by catch per trip is fairly consistent through the range were harvest occurs. In addition, the distribution maps of VTR number of trips and catch over time show a decline in both trips and catch that is consistent with the landings data (Figures 4-8).

1.1.3 Revenue

In 2021, commercial vessels landed about 1,090 mt (2.4 million lbs.) of bluefish valued at approximately $2.3 million in 2020 constant dollars. The average annual ex-vessel price of bluefish, coast-wide, was $0.93/lb ($2.05/kg) in 2021. The relative value of bluefish is very low among commercially landed species, approximately 0.081% of the total 2021 value of all federally sold finfish and shellfish landed along the U.S. Atlantic coast. A time series of commercial bluefish landings, revenue, and ex-vessel price from 2000 to 2021 is provided in Figure 9.

1.1.4 Commercial Biological Sampling

1.1.4.1 Maine to Virginia

Commercial fisheries from Maine to Virginia were sampled as part of the NEFSC data collection program. In addition, the Virginia Marine Resources Commission's (VMRC) Stock Assessment Program (SAP) has collected finfish biological data (length, weight, sex, and age) since 1988. At most sites, bluefish are sampled from 50-pound boxes of landed fish that have been graded, boxed, and iced. At sites associated with pound net or haul seine landings, bluefish are intercepted after they have been graded by market category and weighed. A 50-pound box (or partial box) of graded fish from all available species market categories (i.e. small, medium, large, and unclassified) are chosen for determination of length, weight, and sex information. In most cases, the entire 50-pound box of fish graded by species market category is sampled to account for within-box variation (see Chittenden and Barbieri 1990).

Each fish is measured for size (total length and usually weight). Weight is measured to the nearest 0.1 lbs; total length is measured to the nearest millimeter (mm), accurate to 2.5 mm, using electronic Fish Measuring Boards. Fork length is measured on a subsample basis. All fish, except those with damaged tails, are measured for total length from the tip of the snout to the end of the tail fin.

For ME-VA bluefish, the numbers of fish sampled has ranged from a low in 1995 of 189 fish to a maximum of 8,022 fish in 2012 (Table 5). Sampling has averaged just over 3000 fish per year since the year 2000. Expansion of length data was completed by market category and quarter of the year, with the results merged into half year periods. Market category/quarters with inadequate length samples were filled with length information from adjacent quarters within the same market category. Market category/quarters with landings and no associated lengths were combined with landings information from adjacent quarters.

1.1.4.2 North Carolina

Commercial bluefish landings are monitored through the North Carolina trip ticket program (1994-present). Under this program, licensed fishermen can only sell commercial catch to licensed North Carolina Division of Marine Fisheries (NCDMF) fish dealers. The dealer is required to complete a trip ticket every time licensed fishermen land fish. Trip tickets capture data on gears used, area fished, species harvested, and

total weights of each individual species landed, by market grade. Trip tickets are submitted to NCDMF monthly.
Fishery-dependent sampling of NC commercial fisheries has been ongoing since 1982. Predominant gears sampled include: ocean sink nets, estuarine gill nets, winter trawls, long haul seines/swipe nets, beach haul seines, and pound nets. From the fishery-dependent data, NCDMF derives length and weight estimates by market grade for almost all of the commercial landings except catches by shrimp trawls, pots, long line, gigs, fyke nets, hand harvest, trolling, and rod & reel. Landings from these unsampled or 'other' commercial gears combined represent 0.2-1.1% of the 1997-2004 landings. Length frequency distributions from all sampled commercial gear were combined to represent landings by these other gears.
Bluefish length frequency samples, by gear, market category and year were obtained from dealers with a sample representing the landings from an individual trip. Sampling was done by market category as fish were culled at the dealers. Length distributions (and aggregate weights) from sampled trips by gear and market grade were expanded by respective landings, gear, and market grade. Length frequency distributions were combined to represent total landings, market grade, quarter, and year.

The number of bluefish sampled by NCDMF has ranged from a low in 2021 of 296 fish to a maximum of 11112 fish in 2001 (Table 5). The very low number of length samples in 2021 likely reflects the impact of COVID on sampling. Sampling has averaged 6,774 fish per year since the year 2000. Expansion of length data was completed by market category and quarter of the year, with the results merged into half year periods. Market category/quarters with inadequate length samples were filled with length information from adjacent quarters within the same market category. Market category/quarters with landings and no associated lengths were combined with landings information from adjacent quarters.

1.1.4.3 Florida

Biological data collection for the bluefish fishery from Florida to North Carolina is sparse. FWC has collected an average of 322 lengths per year from 1992 to 2021. However, there is a large range of values depending on year, from a minimum of 5 fish in 1994, to a maximum of 889 fish in 2015. There is no market category or quarter information associated with the FL lengths and lengths are provided by half year. For years 1985-1991 Florida landings were expanded using NC length information. For 1992-2021, expansion of FL length data was completed by half year. If half year information for length or landings were inadequate, expansion was carried out at an annual level.

1.1.5 Commercial length frequency distribution

The length frequency distribution from the commercial fisheries is characterized by a bi-modal distribution for much of the time-series. In the more recent years (2012-2021), the larger mode is reduced, leading to a skewed distribution with a peak around 35 cm (Figure 10). This pattern in bluefish length frequency has been observed to a lesser degree in some years of the recreational landings length frequencies (Figure 25), and the recreational discard length frequencies (Figure X). The bi-modal pattern is likely a result of low availability to the fisheries of age 3 to age 4 bluefish. Bluefish are known to school by size class and it is speculated that movement dynamics at this age/size range affects availability of these fish. This size cohort could be staying in the south (SC-FL) or offshore each in certain years and since the dominant fisheries for bluefish are coastal, and north of Cape Hatteras, North Carolina, this would account for a reduced availability of this size/age class.

1.1.6 Commercial Discards

Previous bluefish technical committees and working groups have concluded that commercial discards for bluefish along the Atlantic coast were insignificant, and historically this portion of the commercial catch has been ignored. The 2022 RT WG concluded that although commercial discards are a small fraction of the total catch, they should still be estimated and included in the commercial catch totals. To estimate

commercial discards for bluefish, the Standardized Bycatch Reporting Method (SBRM) approach (Wigley et al. 2008) was applied, using the combined (D2) estimator. Commercial discard rates from 1989-2021 were calculated by half-year, gear (Long-lines, Hand-lines, Trawls, Gillnets, and Midwater Trawls), mesh (SM, LG, XLG) and region, NE (Stat Areas: '464', '465', '510', '511', '512', '513', '514', '515', '520', '521', '522', '525', '526', '561', '562', '551', '552', '530', '533', '534', '537', '538', '539', '541', '542', '543') and MA (Stat Areas: '600', '610', '611', '612', '613', '614', '615', '616', '620', '621', '622', '623', '624', '625', '626', '627', '628', '629', '630', '631', '632', '633', '634', '635', '636', '637', '638', '639', '640'). A commercial discard mortality estimate of 0.32 was estimated via meta-analysis of similar species and gears and applied to the annual discards (Appendix 1). Commercial landed lengths were used for the dead discards.

Commercial bluefish dead discards have ranged from a high of 166 MT in 1996, to a low of 7 MT in 2017 (Table 13, Figure 13). Trawl and gillnet fisheries account for almost all of the discards, with small contributions from handline, longline, and midwater fisheries (Figure 14). Observed trips average around 1800 per year over the time series (Figure 15), with regional and temporal trends shown in Figures 16-18. Commercial bluefish discards average 1.5% of the commercial catch, and 0.2% of the total catch. While this portion of the catch is insignificant, the inclusion of these data will allow future shifts in magnitude to be monitored and accounted for in the assessment.

1.1.7 Commercial CAA and WAA

Seasonal length-weight parameters (Working Paper 5 Truesdell et al. 2022) used to calculate numbers at length for the commercial catch are presented in Table 5. Final commercial catch-at-age and weight-at-age matrices calculated using the seasonal multinomial age length keys (Working Paper 14 Celestino et al. 2022b) are presented in Tables 6 and 7.

1.2 Recreational Data (MRFSS/MRIP)

1.2.1 Recreational Data Information

The main source of information on catch, harvest, release numbers, harvest weights, and sizes for bluefish in the recreational fishery come from the National Marine Fisheries Service's Marine Recreational Information Program (MRIP), which was formerly the Marine Recreational Fisheries Statistical Survey (MRFSS). The MRFSS data collection program began in 1979, though estimates of recreationally caught Bluefish are not available until 1981. In 2005, the National Academy of Sciences' Natural Research Council was commissioned to review the MRFSS and provide recommendations for improving recreational fishing estimates. A major finding of the Council was that intercept methods resulted in a non-representative sample of recreational anglers and their catch-per-trip was not accounted for in the estimation methodology, resulting in potentially biased catch estimates and overestimated precision (MRIP website). Interviewers were instructed to maximize the number of intercepts made and site selection was at the interviewer's discretion. Interviewers were more likely to obtain intercepts from high pressure sites and disregard low pressure sites and the catch-per-trip at the low pressure sites was not adequately represented. The Council's review contributed to the implementation of the MRIP and a new estimation methodology. MRIP uses the same basic data as MRFSS but implements a new catch estimate methodology that better matches the sampling design used in the dockside intercept survey. The MRIP methodology is intended to account for the clustered sample design and the non-equal weighting used to select sample sites.

For a thorough review of the Recreational Data changes over the time-series (e.g., methodology comparisons, calibration changes, etc.) see Working Paper 9 (Drew 2022a).

For a thorough review of the Spatial Distribution of Bluefish from an analysis of the MRIP data see Working Paper 10 (Drew 2022b).

1.2.2 Recreational Harvest (AB1)

Recreational harvest estimates of bluefish have averaged around 20,000 MT (44.1 million pounds) annually since 1985. From the 1980s to the early 1990s, recreational harvest declined by about 60% [avg. 1985-1989 = 52,064 MT (114.8 million pounds); avg. 1990-1994 = 22,285 MT (49.1 million pounds)]. Recreational harvest estimates continued to decline at a somewhat slower rate until reaching a low of 10,695 MT (23.6 million pounds) in 1999, increasing to 21,269 MT (46.9 million pounds) in 2010, and steadily decreasing since then to a value of 5,471 MT (12.1 million lbs) in 2021 (Table 8). In 2021, recreational anglers along the Atlantic Coast caught 6.2 million bluefish, a 34% decrease from 2020. Recreational harvest has decreased over the last 8 years, from a peak of 21.5 million fish in 2014, to the lowest harvest in the time series in 2021 of 6.2 million fish (Table 9). The majority of recreational activity occurred from May to October, with the peak activity in July and August. Most of the recreational activity occurs from July to October, when almost 70% of the bluefish harvest is taken.

1.2.2.1 Recreational Harvest by Mode

Figure 19 reflects recreational harvest (AB1) estimates of total removals by mode and indicates that the primary catch modes for bluefish are private boats and shore-based fishing. Less than 10 % of the catch came from for-hire boats over the time-series.

1.2.2.2 Recreational Harvest by Area

MRIP classifies catch into three fishing areas: inland, near-shore ocean (< 3 mi), and offshore ocean (> 3 mi). About 51% of the catch of bluefish on a coast-wide basis came from inland waters, followed by near-shore ocean (42%) (Figure 20). Offshore ocean is only about 7% of the total catch. The inland portion of the harvest has been decreasing in recent years, with a concurrent increase in near-shore ocean harvest (Figure 20). For a detailed analysis of the spatial distribution of bluefish based on MRIP catch information see Working Paper 10 (Drew 2022b).

1.2.3 Recreational Releases (B2)

MRIP recreational release estimates have ranged from a low of 5.2 million fish (1988) to a high of 42.5 million fish (2001) from 1985-2021 (Table 10). Recreational release estimates have generally increased in proportion to harvested fish over the time series, increasing from approximately 19% of the total coast-wide catch in 1985 to over approximately 80% in 2021. Recreational discards in 2021 were estimated at 14,792 MT and after adjusting for a 9.4% mortality rate the resulting discard loss was 1,391 MT. Recreational discard loss in weight has ranged from a low of 905 MT in 1988, to a high of 7,270 MT in 2001.

1.2.3.1 Recreational Releases by Mode

Figure 21 reflects recreational releases (B2) by mode and indicates that the primary release modes for bluefish are private boats and shore-based fishing. Less than 10 % of the releases came from for-hire boats over the time-series. These trends mimic the mode patterns seen in the harvest.

1.2.3.2 Recreational Releases by Area

MRIP classifies catch into three fishing areas: inland, near-shore ocean (< 3 mi), and offshore ocean (> 3 mi). About 48% of recreational bluefish releases on a coast-wide basis came from inland waters, and 48% from nearshore waters (Figure 22). Offshore ocean is only about 4% of the total releases. For a detailed analysis of the spatial distribution of bluefish harvest and releases based on MRIP data see Working Paper 10 (Drew 2022b).

1.2.4 Recreational Discard Mortality

Since the 1997 assessment (23rd SAW), recreational discard mortality was estimated at 15%. This was based on estimates calculated in a study by Malchoff (1995), and modified by the ASMFC Bluefish Technical Committee. Prior estimates used in 1994 (18th SAW), estimated a hooking mortality rate of 25% and was based on analogy with species such as striped bass (Diodati 1991), black sea bass (Bugley and Shepherd 1991), and Pacific halibut (IPHC 1988).

The SAW60 WG in 2015 conducted a thorough analysis to estimate recreational discard mortality for bluefish. Four methods to calculate a point estimate of post release mortality were conducted, resulting in a range of estimates between 14% and 17%. The TC and WG approved a 15% (SD=0.143%) discard mortality estimate for use in SAW60 based on bluefish specific estimates from five known studies using Bartholomew and Bohnsack (2005) meta-analysis methodology. Supporting analysis using 70 studies and 21 different species from Bartholomew and Bohnsack (2005) (16% post release mortality) and an equal weighted estimate from bluefish specific papers (14% post release mortality) assisted the decision by the WG and TC.

The 2022 research track working group re-visited and updated the recreational discard mortality meta-analysis that was carried out in 2015. The recreational discard mortality was changed from 15% to 9.4% based on this updated analysis. See Working Paper 11 (Valenti 2022b) for full details of how this new estimate was derived.

1.2.5 Recreational Biological Sampling

Recreational landings are sampled for length as part of the MRIP program. The MRIP length samples were used to expand recreational landings per half year. Seasonal and annual length frequency distributions for the recreational harvest are presented in Figures 23-25. In some years of the time-series bluefish harvest lengths exhibit a bi-modal distribution, with a peak of fish around 35 cm, and a smaller peak around 70 cm. This trend has diminished in recent years but is consistent with trends seen in the commercial length frequency distributions. The bi-modal pattern is a result of an apparent low availability to the fisheries of age 3 to age 4 bluefish. Bluefish are known to school by size class and it is likely that unobserved movement dynamics at this age/size range affects availability of the population. It is possible a larger portion of the population at these sizes are staying south or offshore each year. Since the dominant fisheries for bluefish are coastal and north of Cape Hatteras, North Carolina, this would account for a reduced available of this size/age class.

Recreational discards were characterized using lengths from MRIP intercept data, bluefish tagged and released in the American Littoral Society (ALS) tagging program (by definition B2 catches), as well as information provided by volunteer angler programs in RI, CT, and NJ, and SC.

1.2.5.1 MRIP i9 release lengths

The MRIP i9 intercept data includes release length information collected from headboats from 2004-2021. In total, 11,140 release lengths have been collected over the time-series, with 2,135 in the Spring and 9,005 in the Fall (Table 11, Figure 26). The disparity in seasonal sample numbers can be attributed to sampling intensity in the northern states along with bluefish availability later in the season. Seasonal and annual length frequency distributions for MRIP release lengths are presented in Figures 27-29.

1.2.5.2 American Littoral Society Tagging Program

The American Littoral Society (ALS) has been using volunteer anglers to tag, release, and recapture recreationally important fish species along the US East coast since 1965. The program was originally focused on tagging coastal Atlantic sharks. However, during the drastic decline of striped bass in the early 1970's the program shifted its focus to striped bass, and other coastal species like bluefish. Bluefish are among the top recoded species in the ALS database and over the time series account for over 30,000 observed release lengths (Table 12). Seasonal and annual length frequency distributions for ALS releases are presented in Figures 30-33.

1.2.5.3 Rhode Island Volunteer Angler Survey

The Rhode Island Department of Environmental Management Division of Fish and Wildlife (RIDFW) implemented a voluntary on-line angler logbook (eLOGBOOK) in 2010. The eLOGBOOK application, housed by the Atlantic Coastal Cooperative Statistics Program (ACCSP), enables recreational fishers to enter complete trip level catch and effort data online. Information collected includes trip date, fishing mode (party, charter, private, shore), area fished, number of fishers, number of lines, gear type, hours fished, species, disposition, length and quantity.

1.2.5.4 Connecticut Volunteer Angler Survey

The Connecticut DEEP Marine Fisheries Division has conducted a Volunteer Angler Survey (VAS) since 1979. This survey supplements the National Marine Fisheries Service, Marine Recreational Information Program (MRIP) by providing additional length measurement data particularly for fish that are released. The survey's initial objective was to collect marine recreational fishing information concerning finfish species with special emphasis on striped bass. In 1994, the collection of bluefish length measurements was added to the survey to enhance understanding of the bluefish fishery in Connecticut. In 1997, length measurement information for other marine finfish was added to the survey design.

The CT VAS is designed to collect trip and catch information from marine recreational (hook and line) anglers who volunteer to record their fishing activities by logbook. The logbook format consists of recording fishing effort, target species, fishing mode (boat and shore), area fished (subdivisions of Long Island Sound and adjacent waters), catch information concerning finfish kept (harvested) and released, and length measurements of striped bass (since 1979), bluefish (since 1994), and other common species (since 1997). Instructions for volunteers are provided on the inside cover of all postage paid logbooks. Each participating angler is assigned a personal numeric code for confidentiality purposes. After the logbook data are entered into a database, logbooks are returned to each volunteer for their own personal records.

1.2.5.5 New Jersey Programs

Recreational discard data were available from several New Jersey programs: the New Jersey volunteer angler survey (VAS) is an online, open access survey that began in 2006. The intent of the survey is to complement and supplement the MRIP survey. Two main objectives of the VAS are to allow anglers to submit data to increase buy-in to management measures as well as address sample size concerns of MRIP, and to collect additional length frequency data of discarded fish. The survey was designed based on the MRIP intercept survey, collecting effort, catch, and length information from marine recreational (hook and line) anglers in New Jersey waters. The survey is available online at http://www.njfishandwildlife.com/marinesurvey.htm.

The NJ Tournament and Party/Charter Boat biological sampling program is designed to collect marine recreational (hook and line) fishing information concerning finfish species. Tournament sampling consists

of staff collecting biological data (length, weight, age, sex) of finfish kept (harvested) and released during fishing tournaments. In 2014, logbooks were created for tournament anglers who volunteered to record their fishing activities. The logbook format consists of recording fishing location, number of hours fished, fishing mode (surf or boat), number of anglers reporting on log, water temperature, catch information concerning finfish kept and released, and length measurements.

NJ Party/charter boat sampling consists of staff collecting biological data of finfish kept and released during fishing trips aboard party/charter boats. Party/charter boats can submit trip and catch information by logbook when staff are not present. The logbook format consists of recording fishing location, number of hours fished, number of anglers, water temperature, weather conditions, catch information concerning finfish kept and released, and length measurements.

Length frequencies from the recreational catch and discards show a similar trend to the commercial length frequency. While previous years were characterized by a bimodal distribution, more recent years reveal a skewed distribution, with a main peak around 28 cm and a flat/slightly-decreasing distribution out to 90 cm (Figure B4.10A & B). Total length frequency distribution by season of the recreational landings and discards are presented in Figure B4.11. The average size of the recreationally released bluefish is larger than the average size of retained fish, an uncommon pattern most likely due to bluefish's unpalatability at larger sizes.

1.2.5.6 South Carolina Volunteer Angler Program

Recreational release length information from SC comes from the Marine Gamefish Tagging Program. This program was sponsored by the South Carolina Department of Natural Resources. This program has not focused on bluefish, however, anglers have tagged and released almost 3,000 bluefish since 1978. The release length information from these 300 fish was used in the current assessment. This tagging program has diminished in recent years as SCDNR has actively discouraged anglers from tagging bluefish in addition to other species.

1.2.6 Recreational dead discard (B2) weight estimation

The recreational dead discard component of the catch was calculated using the season/region length frequency distributions developed from all of the recreational biological sampling data (Table 12, Figure 50). For each year, expanded lengths were calculated by season/region and summed to get a seasonal total length distribution. Seasonal length-weight parameters (Table 5) were then used to calculate total seasonal weight and summed for a total annual release weight. A discard mortality estimate of 9.4% (Working Paper 11 Valenti 2022b) was applied to calculate the weight of dead discards for the total catch.

1.3 Total Catch

Total bluefish catch by component is presented in Table 13 and Figure 51. Overall, total catch has declined since the beginning of the time series. There was a slow increase in catch from 1996 to 2010, but the declining trend has continued to the lowest values in the time-series in recent years (Figure 51). On average, commercial landings account for 14% of the total catch with commercial discards averaging only 0.2%. The total catch is dominated by the recreational fishery with landings accounting for 71%, and discards averaging 14.8%.

Tables

Table 1. ACCSP Gears included in each of the 2022 Bluefish RT Assessment Gear Categories

BF_2022_RT	ACCSP Gear Types	
Gear Category	Type Code	Gear Type
Gill Nets	006	GILL NETS
Hook and Line	014	BY HAND
Hook and Line	013	HAND LINE
Hook and Line	007	HOOK AND LINE
Pound Nets	003	FIXED NETS
Seines	001	HAUL SEINES
Seines	002	PURSE SEINES
Trawls	004	TRAWLS
Other	010	DIP NETS AND CAST NETS
Other	009	DREDGE
Other	008	LONG LINES
Other	015	OTHER GEARS
Other	005	POTS AND TRAPS
Other	011	RAKES, HOES, AND TONGS
Other	012	SPEARS AND GIGS
Not Coded	000	NOT CODED

Appendix 1: Commercial discard mortality rate

M. Celestino
August 2022

Introduction

The 2015 bluefish working group (WG) assumed that commercial discards were minimal for a variety of reasons set forth in NEFSC (2015). However, in subsequent years, this assumption was increasingly questioned by technical advisory groups. As an example, some New England states began reporting that their commercial quotas were being reached, and were struggling to find donor states from which quota could be transferred. This lack of quota led to commercial fleets in some states to discard their catches of bluefish. Additionally, the assumption of minimal commercial discards was viewed by the MAFMC's SSC as a significant source of scientific uncertainty in the determination of OFL and ABC (NEFSC 2015).
The present WG re-evaluated this assumption, and while the scale of commercial discards appears to be modest relative to commercial and recreational landings (and recreational discards), the WG reasoned that its estimation would resolve a source of uncertainty in the assessment and management of bluefish. In order to include an estimate of dead commercial discards in the bluefish assessment, an estimate of discard mortality was required.

Methods & Discussion

A search of the literature for "bluefish commercial discard mortality" through Google Scholar resulted in no studies specific to bluefish. Initial discussion centered on an assumed 100% commercial discard mortality rate. The WG acknowledged that given the scale of commercial dead discards relative to other sources of fishing mortality the decision was unlikely to influence the model results. Estimates of 100% have been used for other species where information is lacking (e.g., *Stenotomus chrysops*, NEFSC 2015). The WG also considered that an estimate of 100% would not seem credible to the commercial industry and so in an effort to increase stakeholder assessment buy in, sought to develop a meta-analysis estimate from comparable species that included striped bass and gillnet dominated fisheries that school by size and migrate long distances (C. Power, NJFW pers. comm, Florida Museum 2022a, 2022b, SEDAR39 2015).

Striped bass were considered as a candidate species from which to calculate bluefish discard mortality rates due to life history similarities and availability of gear-specific commercial discard mortality estimates. Spiny dogfish are found epibenthically, but do move throughout the water column, up to the surface (Florida Museum, 2022b; Rago et al. 2014). They swim in large schools with individuals of the same size class staying together as they grow. Additionally, they are highly migratory species, found primarily north of Cape Cod in the summer, they move to Long Island in the fall and as far south as North Carolina in the winter. Smooth dogfish have a similar geographic range as bluefish, are somewhat physically larger than bluefish, and perhaps more demersal (SEDAR 39). This species migrates north in the spring and south in the fall; prefers shallow waters of less than 60 feet (18 meters), but may be found to depths of 200 m (Florida Museum, 2022a).

Only species for which experimentally based or informed discard mortality estimates were available were considered. The WG noted that the values for spiny dogfish were round (Table 1), but further investigation indicated that while the estimates for gillnets and trawls were 'arbitrarily assumed' for SAW 18, some preliminary studies were used to lower the estimate on gillnets for SAW 42, and maintain the estimate for trawls. Information indicated that mortality from gillnets may be much lower than previously assumed, so an estimate of 0.30 was assumed for the SAW 42 assessment; information from trawls indicated much

lower mortality too, but dogfish in the various unpublished studies were all captured in relatively small tows (not representative of the otter trawl fishery), therefore 0.50 was retained.

Gear specific mortality estimates were tabled for each species (Table 2; Rago et al. 2014, SEDAR 39 2014; ASMFC 2018, NEFSC 2006). Bluefish commercial discard totals by gear were queried and pooled over the entire duration of the NMFS observer program (1989-2022) to develop weights for a weighted average (Table 2). The weighted average was 32% and this was the value used in the present bluefish assessment.

Tables

Table 1. Changes in spiny dogfish commercial discard mortality estimates at various stock assessment workshops (SAWs).

SAW	Trawl	Gillnet
SAW18	0.50	0.75
SAW42	0.50	0.30

Table 2. Gear-specific discard mortality rates (expressed as fractions) for species considered in calculation of weighted average bluefish discard mortality rate.

Species	Otter trawl	Anchored gillnet	Drift gillnet	Longline	Hook and line	Pound nets	Other
Spiny dogfish	0.50	0.30		0.10	0.20		
Striped bass	0.35	0.4275	0.08		0.09	0.05	0.20
Smooth dogfish	0.19	0.27		0.135	0.17		
Average	0.35	0.33	0.08				0.14*
CV	0.45	0.25	-				0.43
Weight	0.54	0.38	0.06				0.02

*: The average of 'other' was calculated from longline, hook and line, pound nets and other gears.
